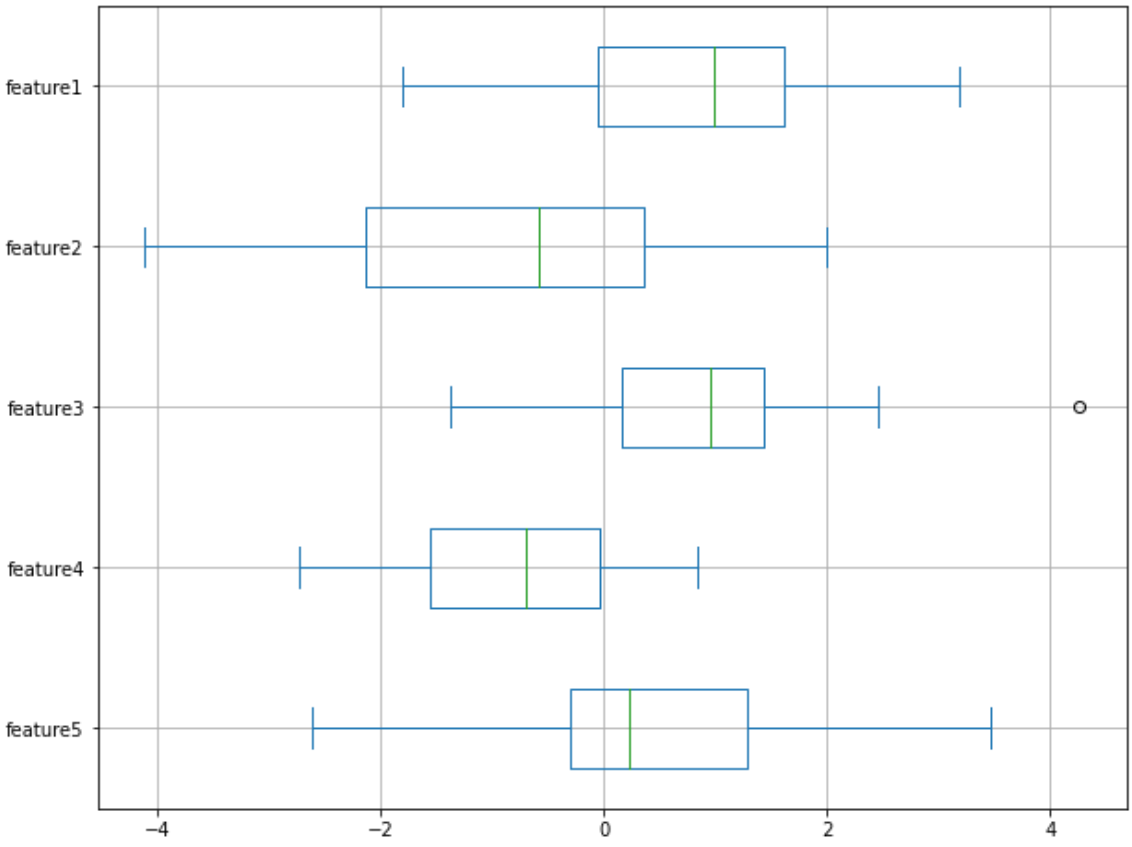
Box plot

In [12]:

```
fig, ax = plt.subplots(figsize=(10, 8))
df[['feature5', 'feature4', 'feature3', 'feature2', 'feature1']].plot.box(vert=False,
                                                                         grid=True,
                                                                         ax=ax)
```

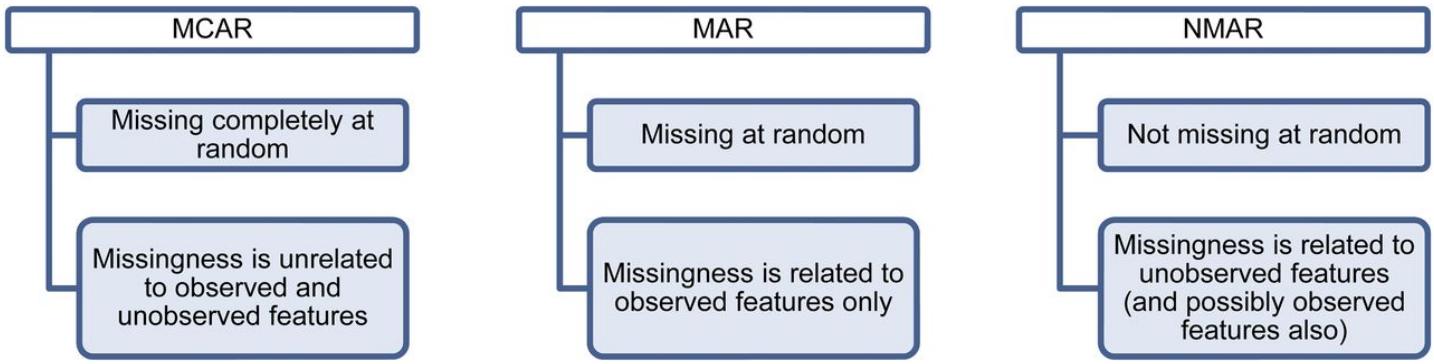
Out[12]:

<AxesSubplot:>



3. Missing Values Analysis

Usually missing data problems areclassified into three categories. We'll try to categorize the missing values in our data.



In [13]:

```
def missing_values_table(df):
    # Total missing values
    mis_val = df.isnull().sum()

    # Percentage of missing values
    mis_val_percent = 100 * df.isnull().sum() / len(df)

    # Make a table with the results
    mis_val_table = pd.concat([mis_val, mis_val_percent], axis=1)

    # Rename the columns
    mis_val_table_ren_columns = mis_val_table.rename(
    columns = {0 : 'Missing Values Amount ', 1 : 'Percent of Total Values'})

    # Sort the table by percentage of missing descending
    mis_val_table_ren_columns = mis_val_table_ren_columns[
        mis_val_table_ren_columns.iloc[:,1] != 0].sort_values(
    'Percent of Total Values', ascending=False).round(1)

    return mis_val_table_ren_columns
```

In [ ]:

```
missing_values_table(df)
```

Out[ ]:

	Missing Values Amount	Percent of Total Values
feature1	5	10.0
feature3	5	10.0
feature5	5	10.0
feature2	4	8.0
feature4	3	6.0

Tools

! For better understanding of missing values patterns, we will use the missingno library which allows us to get a quick visual summary of the completeness of our data.

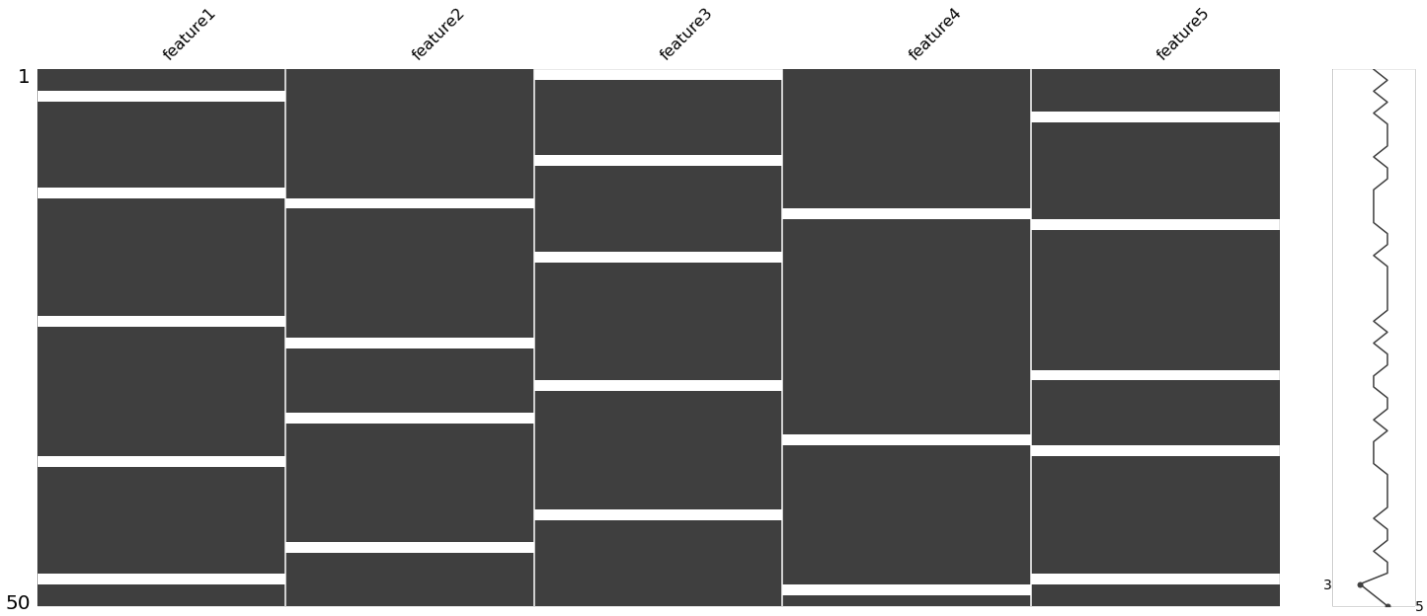
Visualization location of the missing data

In [14]:

```
msno.matrix(df)
```

Out[14]:

```
<AxesSubplot:>
```



Correlation of features missingness.

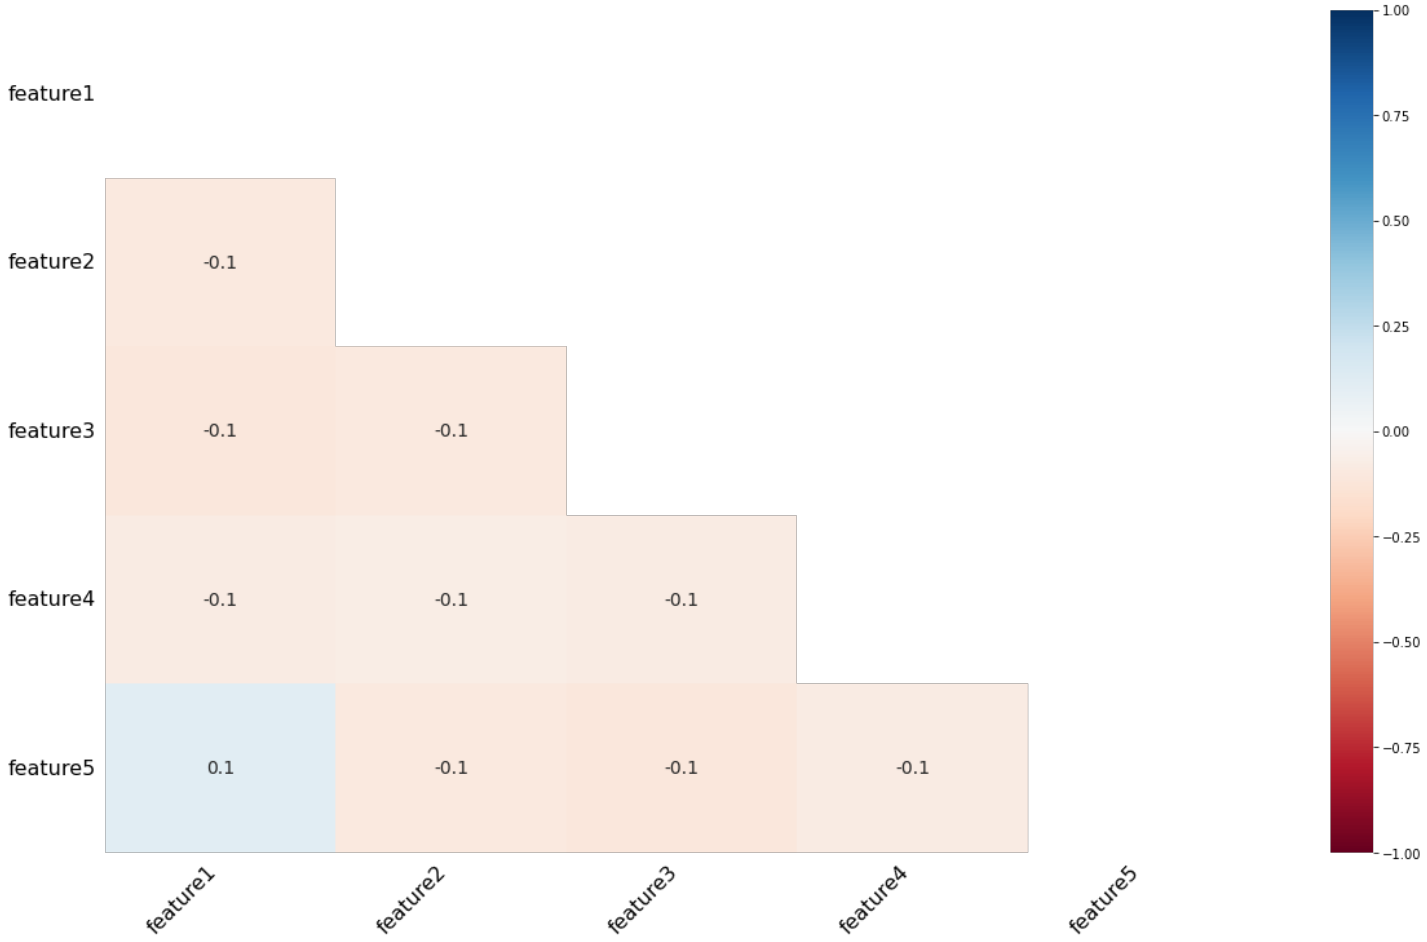
It represents how strongly the presence or absence of one variable affects the presence of another

In [15]:

```
msno.heatmap(df)
```

Out[15]:

<AxesSubplot:>



The heatmap shows that there are no strong correlations between missing values of different features. The low correlations indicate that the data are Missing at Random (MAR).

Features Dendrogram (Hierarchy Clusterization)

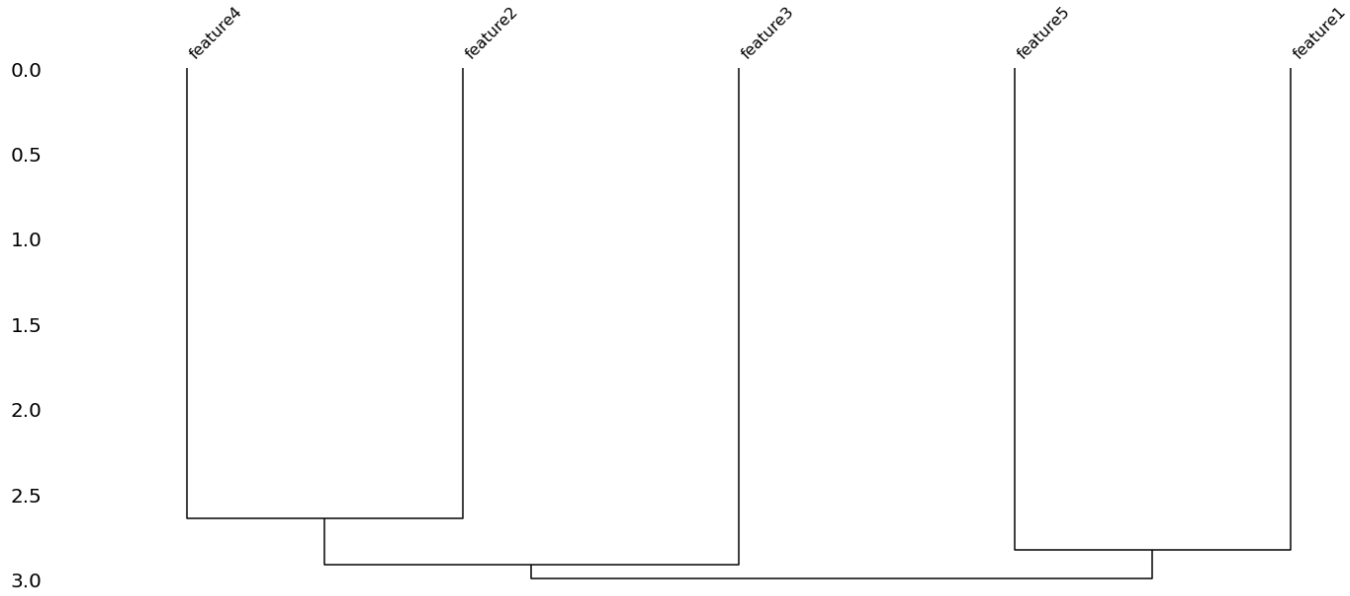
The dendrogram allows you to revealing trends deeper than the pairwise ones visible in the correlation heatmap:

In [16]:

```
msno.dendrogram(df)
```

Out[16]:

<AxesSubplot:>



As the missingno documentaion states:

> **Cluster leaves which linked together at a distance of zero fully predict one another's presence—one variable might always be empty when another is filled, or they >might always both be filled or both empty, and so on(missingno documentation)**

So the conclusion after these analysis charts is that there are no strong correlation between the missingness in features. First of all, due to small amount of missing values.

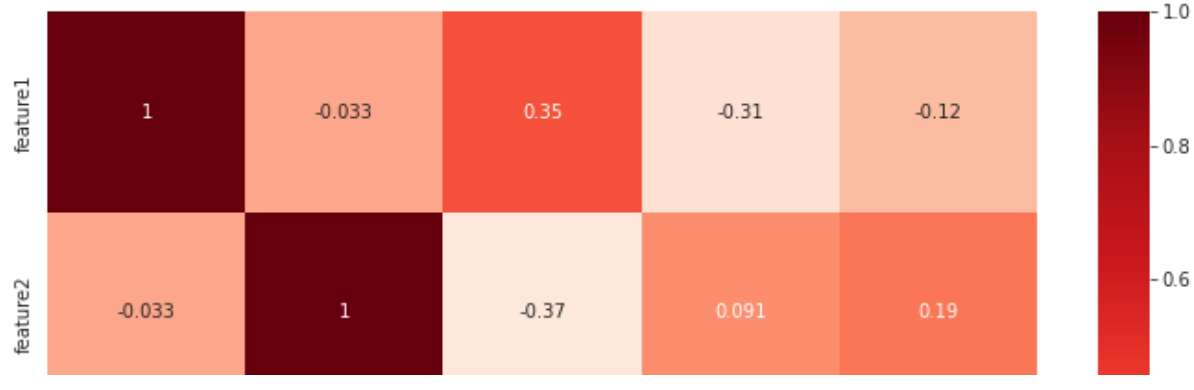
Feature Correlation heatmap

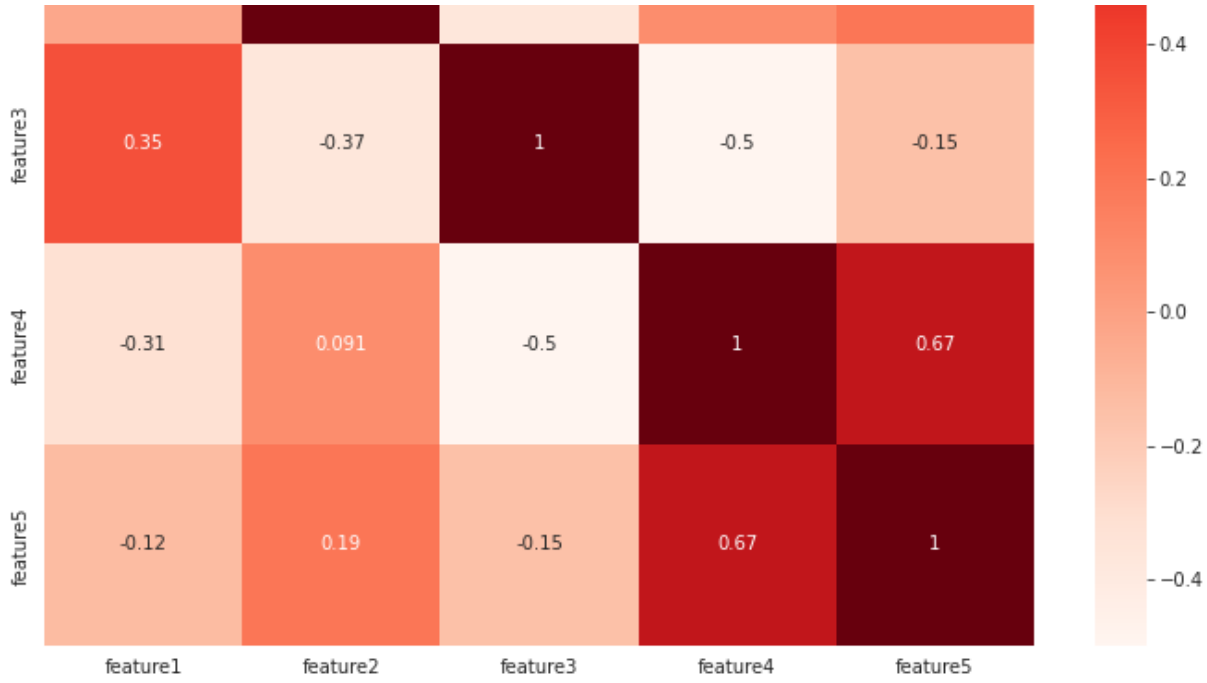
In [69]:

```
def draw_corr_mat(df):
    plt.figure(figsize=(12,10))
    cor = df.corr()
    sns.heatmap(cor, annot=True, cmap=plt.cm.Reds)
    plt.show()
```

In [70]:

```
draw_corr_mat(df)
```





By the way, some features itself have strong enough correlation. For example:

- **feature4 and feature5 have strong positive correlation with 0.67 value**
- **feature4 and feature3 in contrast have negative correlation with 0.5 value**

4. Imputation Methods

There are a lot of missing data imputation scenarios. In this lab the following methods will be implemented:

1. **Basic Data Imputatuion Techniques**
   - **With a constant value**
   - **With a descriptive statistics (mean, median)**
2. **Advanced Data Imputatuion Techniques**
   - **EM Algorithm**
   - **KNN Imputater**
   - **MissForest Imputer**

In [81]:

```
def draw_data_distrib(df):
    fig, axes = plt.subplots(1, 5, figsize=(10,4.5), dpi=140, sharex=True, sharey=True)
    colors = ['dodgerblue', 'orange', 'deeppink', 'green', 'red']
    for idx, (feature, ax, color) in enumerate(zip(df, axes, colors)):
        sns.distplot(df[feature], ax=ax, color=color)
        axes[idx].axvline(x=df[feature].median(),
                color='blue',
                ls='--',
                lw=1.7,
                label='median')

        axes[idx].axvline(x=df[feature].mean(),
                    color='red',
                    ls='--',
                    lw=1.7,
                    label='mean')
        axes[idx].legend()
    plt.tight_layout()
```

Check the data distribution

In [82]:

```
```

```
draw_data_distrib(df)
```

```
/home/alexander/HSE_Stuff/envs/data_analysis/lib/python3.7/site-packages/seaborn/distribu
tions.py:2619: FutureWarning: `distplot` is a deprecated function and will be removed in
a future version. Please adapt your code to use either `displot` (a figure-level function
with similar flexibility) or `histplot` (an axes-level function for histograms).
  warnings.warn(msg, FutureWarning)
/home/alexander/HSE_Stuff/envs/data_analysis/lib/python3.7/site-packages/seaborn/distribu

  warnings.warn(msg, FutureWarning)
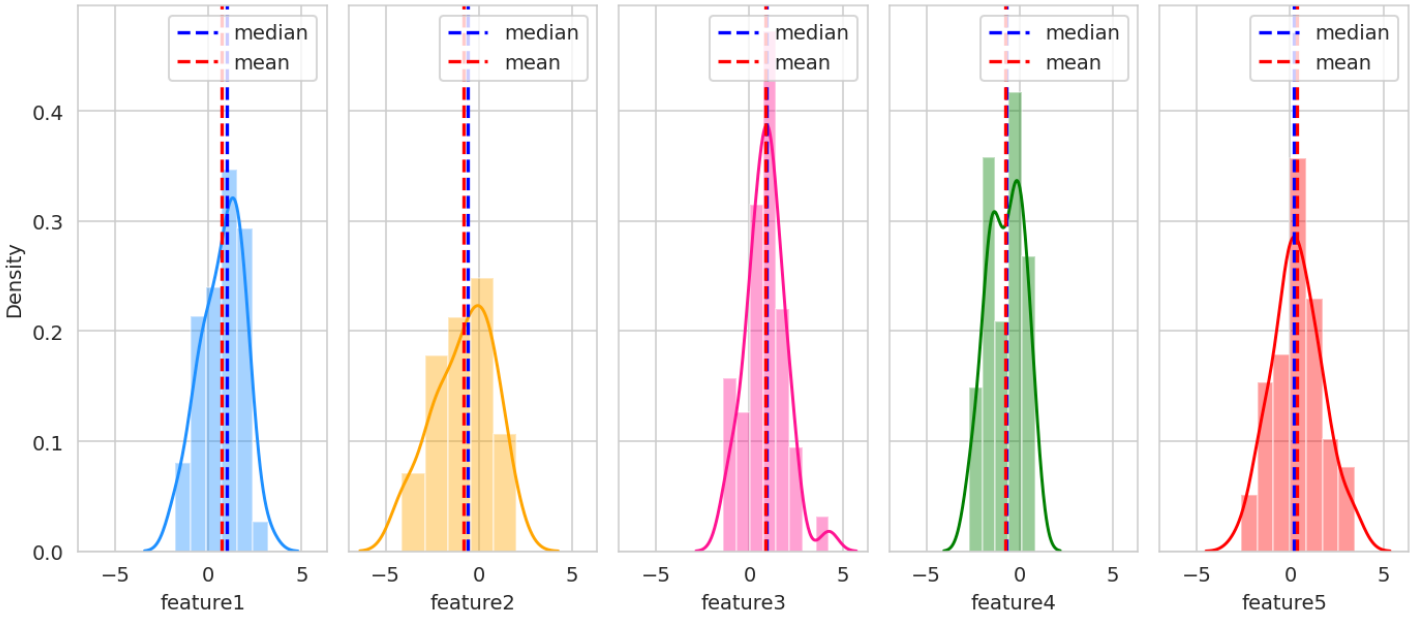
```



The data looks to be is not skewed. So, in case if data right or left skewed(long tail in some side) the mean imputation may be not the best choise.

5, 6. Basic Data Imputatuion Techniques

Random Constant Imputation

In [20]:

```
from sklearn.impute import SimpleImputer
import random
constant_fill_value = random.uniform(-10, 10)
logger.info(f"The data will be filled with {constant_fill_value}")
contant_imputer = SimpleImputer(missing_values=np.nan, strategy='constant', fill_value=co
nstant_fill_value)

contant_imputer.fit(df)
filled_constant_np_data = contant_imputer.transform(df)
```

```
2021-09-27 11:59:30.802 | INFO     |    main   :<module>:4 - The data will be filled with -
```

```
8.623089224747451
```

In [21]:

```
constant_filled_df = pd.DataFrame(data=filled_constant_np_data,columns=col_names)
```

In [22]:

```
constant_filled_df.head()
```

Out[22]:

	feature1	feature2	feature3	feature4	feature5
0	1.117915	-2.065559	-8.623089	-1.362986	-0.709196
1	-0.503055	-2.892927	0.713895	-1.631237	-1.790220
2	-8.623089	-0.077614	0.772394	-1.500325	-0.164499
3	1.163245	1.046673	1.674523	-1.867193	-0.534950
4	0.185329	-2.824514	2.036840	-2.040093	-8.623089

Mean Imputation

In [23]:

```
mean_imputer = SimpleImputer(missing_values=np.nan, strategy='mean')

mean_imputer.fit(df)
filled_mean_np_data = mean_imputer.transform(df)
mean_filled_df = pd.DataFrame(data=filled_mean_np_data,columns=col_names)
```

In [24]:

```
mean_filled_df.head()
```

Out[24]:

	feature1	feature2	feature3	feature4	feature5
0	1.117915	-2.065559	0.867845	-1.362986	-0.709196

KNN Imputation

KNN Imputation

Using this method the missing values will be replaced by the mean value of N nearest neighbors measured by Euclidean distance.

In [28]:

```
from sklearn.impute import KNNImputer
knn_imputer = KNNImputer(n_neighbors=5)
knn_filled_df = pd.DataFrame(knn_imputer.fit_transform(df),columns = df.columns)
knn_filled_df.head()
```

Out[28]:

KNN Imputation

Advantages:

- **It's a great step from the simple average or median imputation**

Disadvantages:

- **Need to choice the K value**
- **It is sensitive to outliers**

MissForest Imputation(Random Forest imputation)

In [29]:

```
from missingpy import MissForest
random_forest_imputer = MissForest()
rf_filled_np = random_forest_imputer.fit_transform(df)
rf_filled_df = pd.DataFrame(rf_filled_np,columns = df.columns)
rf_filled_df.head()

8. Outlier Detection

IQR - Outlier Detection per column

The interquartile range (IQR), also called the midspread or middle 50%, or technically H-spread, is a measure of statistical dispersion, being equal to the difference between 75th and 25th percentiles, or between upper and lower quartiles, IQR = Q3 − Q1.

In other words, the IQR is the first quartile subtracted from the third quartile; these quartiles can be clearly seen on a box plot on the data.

It is a measure of the dispersion similar to standard deviation or variance, but is much more robust against outliers.

In [56]:

```
from collections import namedtuple
filled_dfms = [constant_filled_df, mean_filled_df,median_filled_df, knn_filled_df, em_fil
led_df, rf_filled_df]
fill_types = ["Constant Value", "Mean", "Median", "KNN", "EM", "MissForrest"]
igrs = []
for fill_type, data in zip(fill_types, filled_dfms):
    Q1 = data.quantile(0.25)
    Q3 = data.quantile(0.75)
    IQR = Q3 - Q1
    percentile_data = namedtuple('Data' , 'Q1 Q3 IQR')
    igrs.append(percentile_data(Q1, Q3, IQR))
```

```

Isolation Forest - Outlier Detection per sample

Isolation is the keyword of this algorithm because it isolates anomalies from the rest of the observations. This isolation procedure separates all the data points by randomly splitting the region into smaller pieces.Isolation Forest identifies anomalies as the observations with short average path lengths on the isolation trees . There is a procedure applied for each isolation tree:

1. **Randomly select two features.**
2. **Split the data points by randomly selecting a value between the minimum and the maximum of the selected features.**
